

EWMA response, memory and noise

The exponentially weighted moving average (EWMA) assigns progressively less weight to older observations. Compare $\alpha = 0.2$ in teal with $\alpha = 0.7$ in violet. Both receive the same step from 2 to 8; the parameter controls response time and noise attenuation.

01 Response to a step input

Same input: 2 $\rightarrow$ 8. Only the new-input weight α changes.

The first update reaches 6.2 at $\alpha = 0.7$, but only 3.2 at $\alpha = 0.2$. The faster response also admits more input noise.

Computed · DOI 10.5281/zenodo.18610143

04 Response time and noise attenuation

Independent steady-state noise only; ratio = $\sqrt{\alpha / (2 - \alpha)}$.

Computed · DOI 10.5281/zenodo.18610143

Computed signal analysis; reported benchmarks provide separate implementation context.

Iterflow v1 · doi.org/10.5281/zenodo.18610143 · github.com/mathscapes/iterflow

02 Weight assigned to past inputs

Each strip divides total steady-state weight into past inputs.

Current $\rightarrow$ older inputs; pale tail = lag 5 and beyond.

Computed · DOI 10.5281/zenodo.18610143 · Weight at lag $k = \alpha(1 - \alpha)^k$.

03 Updates required for 95% response

Updates needed to close at least 95% of the original gap.

Computed · DOI 10.5281/zenodo.18610143 · One square = one update; remaining gap = $(1 - \alpha)^k$.

Recurrence and initialization

EWMA uses $s(t) = \alpha x(t) + (1 - \alpha)s(t-1)$, initialized at the first observation. The first new outputs are 3.2 and 6.2. A lag- k input contributes $\alpha(1 - \alpha)^k$; infinite steady-state weights sum to one.

Response time and noise variance

The remaining step fraction is $(1 - \alpha)^k$. Reaching 95% takes 14 updates at $\alpha = 0.2$ and three at 0.7. Independent noise has output variance $\sigma^2\alpha/(2 - \alpha)$. Correlation and warm-up change this analysis.

Implementation benchmarks

Iterflow composes lazy transforms and scalar-state statistics. Manuscript EWMA throughput is 213 vs 951 operations/s for a loop; limited filtering is 7,818 vs 26 for eager arrays. Synthetic Node 22/ARM64 benchmarks, not rerun; these are not noise trials.
